Training and Performance Assessment of Minority Students in STEM

Abstract

The proposed study is designed to implement and test the efficacy of an intervention developed as part of an NSF-funded project by the team of investigators at Longwood University and Virginia State University. This intervention develops the underlying thinking skills in students necessary for success in STEM courses and careers. Rather than relying only on classroom content and high-level thinking skills, this intervention also includes a classroom component involving an innovative video game programming curriculum developed by the investigators. The impact of this intervention will be assessed at a critical developmental period: the entry into high school (9th grade). Over the three-year period of the project, the groups of participants have been assessed on a number of different variables to develop a model of how these variables impact the cognitive interventions. These variables have all been implicated in lowered academic performance, and the information provided by the model will allow the development of future non-academic interventions associated with these variables to enhance the impact of cognitive training.

Introduction

An Information Technology Experiences for Students and Teachers (ITEST) project sponsored by the National Science Foundation (NSF) at Longwood and Virginia State Universities addressed a unique pedagogy and teaching method in science, technology, engineering, and math (STEM) disciplines for middle school students in the Digispired project. The primary goal of project was to provide learning and research opportunities to middle school students by focusing on programming and thus gaming, and the four science themes through Saturday and summer programs for three years. Within this 36-month project, 90 low-income rural and urban students (1) learned about technologies involved in game products; (2) learned about programming, computer graphics, and animation; (3) created games on four science themes – recycling, nutrition, physical exercise or activity, and substance abuse; (4) finalized their interactive game projects for distribution in local educational communities; and (5) shared their learning experiences and products in educational conferences of students and of teachers of mathematics, science, and technology. The project staff developed professional development and instructional resources for replication and identified instructional models and strategies that are appealing to the interactive game generation. This paper discusses the results and ways in which the project related to the natural interests of young people in interactive games and thus motivated them to learn programming and explore technology and software engineering careers.

Evaluation Findings

The following sections detail the findings of the Digispired evaluation during the 2008-2009 school year.

Summer Academy Implementation Quality

Participant feedback on the Digispired Summer Academies held in 2007, 2008, and 2009 was collected through the administration of the Summer Academy Participant Feedback survey, administered near the end of each summer’s activities. Comparisons of all indicators are presented in separate tables for positive and negative indicators (Tables 1 and 2). This arrangement allows for comparisons by gender, by year, or by both attributes. Participants who did not report gender are not included in Tables 1 and 2.

Notable Findings from Summer Academy Implementation Data

- Participants reported being more “challenged” by the 2009 summer academy than any other year. Females were more likely than males to report being “challenged” across all three years.

- Males were more likely than females in 2009 to be of the opinion that what they learned in the summer academy is “important to their future.”

- Males were more likely in 2009 than in any other year to report that they were interested in what they were learning.

- For males six of the positive indicators increased from the 2008 to 2009 implementation (excluding “what you were learning was important to your life now”). For females, to other positive indicators decreased from the 2008 to 2009 implementation: “eager to learn more about the topic” and “what you were learning was important for you in the future.”

- Additionally, several positive indicators showed decreases from the 2007 to 2009 implementation (excluding “how often did you feel challenged”). These findings indicate that the implementation quality, in general, increased between 2008 and 2009, particularly for male students. The findings could also indicate that the quality of the 2009 implementation was not to the standard of the quality of the 2007 implementation in some aspects.

- Male and female students reported feeling successful in what they were doing at roughly comparable levels in each of the three years.
The most notable change among positive indicators of summer academy implementation quality is the rate at which female students report that they are doing is “important to their life now”—with a decrease over the three years of more than 30% in the number reporting “most of the time” or “always.”

With regard to negative indicators, males indicated a steady increase in “how often did you feel bored,” throughout the three years. Females, however, reported being less bored in 2009 than in 2008, but more bored in 2009 than in 2007.

Both males and females perceived the 2009 summer academy to be more difficult than the previous two years. Throughout the three years, males perceived the summer academies to be more difficult than did the female participants. Interestingly, in 2009 more males than females reported that the summer academy was “too easy,” most of the time or always. Females’ perceptions of how easy the material was decreased steadily over the three years.

### Participant Attitudes and Interests

The Participant Attitudes and Interests Survey (PAI) was administered late in the 2007 implementation year to Digispired participants at all three sites and to a comparison group of students of a similar age from the same school divisions. The PAI was again administered to participants in 2008 and to participants and comparison students in 2009. All administrations of the PAI instrument were web-based, with respondents completing the survey as groups in computer labs, supervised by Digispired or school staff members. In 2009, participants at one site did not complete the survey, resulting in a lower response rate than in previous years.

In 2007, the participant group was compared to the comparison students to determine whether the students selected for the Digispired program were similar to students who were not participating. This early comparison provided a helpful basis for future comparisons and helped clarify assertions about the selection and application process and the degree to which it might influence the make-up of the participant group. If, for example, the selection process recruited—by design or by accident—students who were disproportionally interested in STEM careers before participation, conclusions about the ability of the program to encourage students to pursue such opportunities might be reasonably questioned. Independent-samples t tests found no statistically significant differences between the groups’ mean responses, indicating that where differences between the Digispired participant group and the comparison group were evident, none were significant.¹ This suggests that Digispired students, as assessed in 2007, were “like their classmates,” at least in terms of their attitudes and interests indicated by items on the PAI.

On the other hand, in 2009, Digispired participants and comparison students differed significantly on many PAI items. The significant differences are presented in Table 3. The comparison groups in 2007 and 2009 consisted of different individuals. The 2007 comparison students had more positive attitudes toward technology than the 2009 comparison students, which may help explain the participant-comparison differences in 2009.

Independent-samples t tests were used to determine whether differences existed between participants’ responses in 2007 and 2009. PAI data for both years were available only from Halifax and Hopewell school divisions; therefore, the findings are relevant to those divisions only. There were few significant differences on individual items and no significant differences on composite categories. Compared to 2007, respondents in 2009 were significantly less likely to enjoy computer or video games or to “play around” with science or technology for fun. However, they were also significantly less likely to feel that technology lessened their enjoyment of school activities. See Table 6 for statistical details.

*p < .05.

Using the 2009 PAI data, independent-samples t tests were carried out to determine whether there were gender differences on any items or categories of items. Boys tended to have more positive mean scores than girls. However, as in 2008, gender differences were statistically significant for only a few individual items. For the composite categories, males were significantly more likely than females to have positive feelings about technology, participate in technology-related activities, and have intentions to enroll in STEM-related courses. The significant gender differences are presented in Table 7. Most of the effect sizes (Cohen’s d) of these significant differences are medium or large. The findings that males enjoyed and played video games more than females are also similar to those in 2008. These findings may have implications for Digispired program outcomes, if it is presumed that interest in computer or video games is a key motivator—or mediating outcome—theoretically linking program activities and more distal outcomes such as participation in STEM-oriented courses in high school or pursuit of STEM careers.

**Notable Findings from Participant Attitudes and Interests Data**

- For the *Digispired* program as a whole, there was a significant difference between participant and comparison ratings of how important it was for them to “learn about technology.” It was significantly more important to *Digispired* participants than the comparison group.

- *Digispired* participants had significantly less negative feeling about technology than the comparison group.

- Participants reported lower ratings than their comparison counterparts to the following items: “how much longer does it take you to finish schoolwork when it involves technology?” “how much would you rather NOT use technology?” and “how much harder is it for you to learn new things when using technology.”

- When comparing male and female participants across the three years, males reported a steady increase in how much they “enjoy doing things with technology” across all three years. Females, however, indicated that they “enjoyed doing things with technology” less in 2009 than in 2008. The same pattern is true for the question, “*Digispired* increased interest in computer, science, or technology courses.”

- Across the three years, both males and females showed steady increases in their agreement with the following statements: “I am more likely to get a good job after learning how to use technology” and “It is important to learn about technology.”

- Females reported a steady decline in how much they agreed with the following statements: “I get nervous when working with technology” and “I get easily frustrated with technology.” Overall, males showed a decrease in how much they agree with those statements from 2007 to 2009; however, they most agreed with those statements during the 2008 survey session.

- Males were significantly more likely than females to have positive feelings about technology, participate in technology-related activities, and have intentions to enroll in STEM-related courses.

**Participant Knowledge and Skills**

The *Participant Knowledge and Skills (PKS)* assessment was administered to *Digispired* participants in 2007, 2008, and 2009; and administered to the comparison students in 2007 and 2009. Complete PKS data for both groups are included in Appendix F. Descriptive statistics for each group are illustrated in Table 8.

</tr>
</tbody>
</table>

For the 2009 data, independent t-tests found that the differences in the mean of scores achieved by Digispired participants (77.21%) and the mean of comparison group students’ scores (48.25%) were statistically significant, suggesting that Digispired students were different from their classmates ($t \[117\] = -8.429, p = .000). It is important to note that the comparison group for 2009 was not the same comparison group from 2007. Independent t-tests found that there were no significant differences between the two control groups ($t \[112\] = 1.529, p = .129). This statistic argues that even though the comparison groups were not composed of the same individuals, the groups were similar enough to provide a reasonable comparison. Given the 2009 data, it can be said with some confidence that Digispired participants are different from their comparison peer—at least in terms of the computer knowledge and skills assessed by the PKS. Specifically, Digispired participants are significantly more knowledgeable about technology and related skills. This finding is important, particularly given the fact that the two groups were statistically similar before implementation of the Digispired program.

Additionally, differences in the measured scores of Digispired participants’ PKS scores in 2007 (63.75%) and in 2009 (77.21%) are indeed statistically significant ($t \[133\] = 4.632, p = .000). This means that the pre-participation and post-participation differences, while not absolutely attributable to Digispired program activities, are large enough that they are not likely explained away by variances occurring naturally among group members. Thus, participation in the Digispired program seems to have increased students’ knowledge and skills relevant to technology.

Figure 1 examines differences among the Digispired participants for all three years. Distributions of PKS scores among the Digispired group and comparison group are provided in Figure 2. Male and female comparisons were not conducted because gender was not asked on the PKS.

**Notable Findings from Participant Knowledge and Skills Data**

- Digispired participants have significantly improved their computer knowledge and skills, at least as they are assessed by the PKS. The Digispired participants showed significant increases in their PKS scores from 2007 to 2009.

- For the 2009 data, Digispired participants scored significantly better than the comparison group, suggesting, with some confidence, that Digispired participants are more knowledgeable about technology their comparisons—at least in terms of the computer knowledge and skills assessed by the PKS. The groups were not significantly different before the Digispired program.

Conclusions and Summary

The most notable success of the program was observed in the area of improving students’ knowledge and skills. From 2007 to 2009, participating students’ knowledge of technology and the skills required to use technology successfully increased significantly. Mean scores on the assessment increased steadily over the 3 years of the project. In 2009, participating students also demonstrated significantly better knowledge and skills than their comparison peers.

At the close of the project, participating students also held attitudes toward technology that were significantly more positive than those held by their comparison peers. Among other factors, Digispired students were more likely to believe that it was important to learn about technology, to be less scared of or frustrated by technology, to report that technology increased their ability to learn new things, to report that technology increased their ability to learn new things, to report being more likely to enroll in STEM-related courses, and to have more positive feels toward technology in general. Digispired students also reported a much greater interest in pursuing careers in scientific research or engineering than their comparison peers (59% to 45%). Participants were more certain about their post-high school plans than non-participants; they primarily planned to attend 4-year college or university programs (78% versus 49% of comparison students).

Students’ comments indicate that they enjoyed the program, for the most part, and that they increased their knowledge and skills through their participation. Students enjoyed doing hands-on projects and appreciated working in groups and learning from their peers. The Lego Robotics competition was popular with several students, as were the field trip experiences (which students also saw as opportunities to learn what they would like to have in an institution of higher education). Nearly all students believed that learning about technology would help them in their future education and careers (even if it did not seem relevant to their lives at the moment). It is important to note that in addition to feeling more confident in mathematics and science, students reported other important and, perhaps, unintended impacts of the program including increased patience (especially in peer workgroup situations) and increased maturity.
